

**Mathematics.** — *Demonstration that the concept of spreads of higher order does not come into consideration as a fundamental notion in intuitionistic mathematics.* By Prof. L. E. J. BROUWER\*

(Communicated at the meeting of September 26, 1942.)

In my note, “*Concerning the free development of spreads and functions*”,<sup>1)</sup> the process  $M_\sigma$  was considered, through which the fundamental sequence  $F'$ , which is enumerated in an arbitrary, predetermined way, is associated one-to-one with finite choice sequences of numbers and likewise an arbitrary element  $\sigma$  of the spread<sup>2)</sup>  $M$ . We want to call this process  $M_\sigma$  a spread of second order, and the successive sequences of figures thus associated to the unrestricted choice sequences of numbers [we shall call] *the elements of the second-order spread*  $M_\sigma$ .

The assertion stated in my quoted note, that  $M_\sigma$  acts as a subspecies of a spread  $M_1$  which is derivable from  $M$ , and that the union of all  $M_\sigma$  generated from  $M$  is identical with this  $M_1$ , shall be demonstrated as follows. First, we will deal with the construction of the spread  $M_1$ .

Let  $\alpha_1 \alpha_2 \dots \alpha_m$  be a finite choice sequences of numbers. We will notate the rank thereof in the fundamental sequence  $F'$  with  $\varrho(\alpha_1 \alpha_2 \dots \alpha_m)$  and the maximum of the numbers  $\varrho(\alpha_1)$ ,  $\varrho(\alpha_1 \alpha_2)$ ,  $\dots$   $\varrho(\alpha_1 \alpha_2 \dots \alpha_m)$  with  $\zeta(\alpha_1 \alpha_2 \dots \alpha_m)$ .

We will call the combination of an arbitrary number  $\alpha_1$  with  $\varrho(\alpha_1)$  arbitrary numbers  $\beta_1, \beta_2, \dots, \beta_{\varrho(\alpha_1)}$  a  $K$ -combination. We enumerate the  $K$ -combinations through a fundamental sequence  $F$ . We notate any  $K$ -combination which receives the rank  $\nu_1$  in  $F$  with  $K_{\nu_1}$ .

For a given  $\nu_1$ , and thence also a given  $\alpha_1$ , and arbitrary  $\alpha_2$ , we call the number  $\alpha_2$  a  $K_{\nu_1}$ -combination in case  $\zeta(\alpha_1 \alpha_2) = \zeta(\alpha_1)$ , and likewise, in case  $\zeta(\alpha_1 \alpha_2) > \zeta(\alpha_1)$ , we call the combination of  $\alpha_2$  with  $\zeta(\alpha_1 \alpha_2) - \zeta(\alpha_1)$  arbitrary numbers  $\beta_{\zeta(\alpha_1)+1}, \dots, \beta_{\zeta(\alpha_1 \alpha_2)}$  a  $K_{\nu_1}$ -combination. For each  $\nu_1$  we enumerate the  $K_{\nu_1}$ -combinations through a fundamental sequence  $F_{\nu_1}$ . We notate each  $K_{\nu_1}$ -combination, which receives rank  $\nu_2$  in  $F_{\nu_1}$ , with  $K_{\nu_1 \nu_2}$ .

For arbitrary  $\nu_1$  and  $\nu_2$ , and thence also given  $\alpha_1$  and  $\alpha_2$ , and arbitrary  $\alpha_3$ , we call the number  $\alpha_3$  a  $K_{\nu_1 \nu_2}$ -combination in case  $\zeta(\alpha_1 \alpha_2 \alpha_3) = \zeta(\alpha_1 \alpha_2)$ , and, in case  $\zeta(\alpha_1 \alpha_2 \alpha_3) > \zeta(\alpha_1 \alpha_2)$ , we likewise call the combination of  $\alpha_3$  with  $\zeta(\alpha_1 \alpha_2 \alpha_3) - \zeta(\alpha_1 \alpha_2)$  arbitrary numbers  $\beta_{\zeta(\alpha_1 \alpha_2)+1}, \dots, \beta_{\zeta(\alpha_1 \alpha_2 \alpha_3)}$  a  $K_{\nu_1 \nu_2}$ -combination. For

<sup>1)</sup> Proc. Ned. Akad. v. Wetensch. Amsterdam, **45**, 322 (1942).

<sup>2)</sup> For the sake of simplicity, we restrict ourselves in this note to such spreads, in the process of whose creation neither inhibition nor termination occurs. This restriction is inessential.

each pair of numbers  $\nu_1, \nu_2$  we enumerate the  $K_{\nu_1 \nu_2}$ -combinations through a fundamental sequence  $F_{\nu_1 \nu_2}$ . We notate each  $K_{\nu_1 \nu_2}$  combination which receives the rank  $\nu_3$  in  $F_{\nu_1 \nu_2}$  with  $K_{\nu_1 \nu_2 \nu_3}$ .

Proceeding in this way, we define  $K_{\nu_1 \nu_2 \dots \nu_s}$  for each natural number  $s$ . In doing so, we take care from the outset to determine a law through which the fundamental sequences  $F_{\nu_1 \nu_2 \dots \nu_s}$ , each enumerating  $K_{\nu_1 \nu_2 \dots \nu_s}$ , shall be defined once and for all.

The construction of  $M_1$  will now be carried out, in which we shall associate each sequence of figures with the finite sequence  $\nu_1 \nu_2 \dots \nu_s$ , which is associated to the finite choice sequence  $\beta_1 \beta_2 \dots \beta_{\ell(\alpha_1 \alpha_2 \dots \alpha_s)}$  for the respective numbers  $\alpha_1 \alpha_2 \dots \alpha_s$ ,  $\beta_1 \beta_2 \dots \beta_{\ell(\alpha_1 \alpha_2 \dots \alpha_s)}$  in  $M$ .

Let  $\sigma$  be the element of  $M$  generated by the infinite choice sequence  $\gamma_1 \gamma_2 \gamma_3 \dots$ . Then, the second-order spread  $M_\sigma$  is identical with a subspecies  ${}_\sigma M_1$  of  $M_1$ . This  ${}_\sigma M_1$  arises when for each  $s$  in  $M_1$  only such  $\nu_s$  may be chosen to which  $K_{\nu_1 \nu_2 \dots \nu_{s-1}}$ -combinations correspond, in which each  $\beta_\tau$  is equal to the  $\gamma_\tau$  which carries the same index.

Conversely, let  $e$  be an arbitrary element of  $M_1$ . Then the unrestricted choice sequence  $\nu_1 \nu_2 \nu_3 \dots$  which generates  $e$  in  $M_1$  is defined following the aforementioned definition of  $\nu_s$  simultaneously with an unrestricted sequence of numbers  $\beta_1 \beta_2 \beta_3 \dots$ , which in turn generates the element  $\sigma(e)$  in  $M$ . The associated  $M_{\sigma(e)}$  receives  $e$  as an element. Consequently,  $M_1$  is identical to the union of all  $M_\sigma$  generated from  $M$ .

From the above, it follows that the concept of spreads of second order does not come into consideration as a fundamental notion in intuitionistic mathematics.

In order to define the concept of *spreads of higher order*, we accept that the concept of *spreads of  $n$ th order* may be defined already, and consider the process  $(M^{(n)})_\sigma$ , through which the fundamental sequence  $F'$ , which is enumerated in an arbitrary and predetermined way, will be associated one-to-one with finite choice sequences and likewise an element  $\sigma$  an element  $\sigma$  of the  $n$ th-order spread  $M^{(n)}$ . We will call this process  $(M^{(n)})_\sigma$  an  $(n+1)$ th-order spread, and we will call the successive sequences of figures which are thus associated to the unrestricted choice sequences of numbers *the elements of the  $(n+1)$ th-order spread  $(M^{(n)})_\sigma$* .

However, now a spread of second order  $M_\sigma$  is a subspecies of a spread  $M$  which takes  $M_\sigma$  as its basis, and is derivable from the spread  $M_1$ , i.e. an arbitrary element  $\pi$  of  $M_\sigma$  is simultaneously an element of  $M_1$ . Hence, it follows that the third-order spread  $(M_\sigma)_\pi$  is identical with the second-order spread  $(M_1)_\pi$ , i.e. an arbitrary third-order spread is identical with a second-order spread. And hence it follows

moreover that also for arbitrary  $n$  an arbitrary  $n$ th-order spread is identical with a second-order spread.

Consequently, it emerges that also the concept of higher-order spreads, in contrast to the concept of higher-order species, does not come into consideration as a fundamental notion in intuitionistic mathematics.
